Roll No. 101

Q1. b) Central Processing Unit

Q2. RAM stands for Random Access Memory. It is volatile memory that temporarily stores data and instructions the CPU is currently using. When the power goes

off, everything in RAM is erased.

Q3. The operating system manages the computer's hardware and software. It handles memory management, decides which process runs when (scheduling), manages files on the disk, and gives the user an interface to interact with

the computer.

Q4. A compiler converts the whole program into machine code at once before

running it, and creates an executable file.

If there are errors, they all show

up after compilation. An interpreter

instead reads and runs the code one line

at a time, without making a separate executable, and stops as soon as it hits

an error.

Qs. The OSI model has 7 layers.

Physical layer sends raw bits over the wire.

Data link layer handles node to node transfer and checks for errors.

Network layer does routing and IP addressing. Transport layer ensures end to end delivery using TCP or UDP. Session layer manages the connection

between two applications. Presentation layer handles encryption and data

format conversion. Application layer is where user apps like browsers and email interact, using things like HTTP.
