21/ supervised learning is using tabular data for prediction. It will predict the model input based on the label and output are already desired.

Example: linear regression, logistic regression.

27/ Outlier can be an observation of a data point that lies on an abnormal distance from other data points. We can find it by performing some operation. And it can be box plot and whisker plot to find out and detect the outlier.

31/ K in k-mean algorithm means number of clusters center.

34/ Based on the given classifiers all those 3, we can see that the 1st one is the best one:

- 1st: the boundary is wider and its next to the ^{data} points.
- 2nd: there's some data point inside the boundary which it should not.
- 3rd: the boundaries are far from data points and the line is too close.

26/ Structured Vs Semi-Structured data.

- + structured data
- is a form of excel, csv, relational database
- easy to read
- a standard data
- has corresponding data types

- + semi-structure data
- form of JSON, XML
- can only be understood by computer
- not fully standard
- does not have

28/ Data pre-processing is a process of preparing data before performing any prediction or analysis. The steps of data pre-processing include data cleansing, finding missing values, outlier detection, normalization, data splitting and many more steps before taking the data to the model.

Name: E Sdcmean

ID: 1101901023

29/ Data normalization in K-NN is to transforming the data into a similar scale. In order to perform K-NN operation, if the data is not in a similar scale it's hard to define k and find its neighbor.

25/. Application in Data science:

- health care
- banking

22/. For model M_1 the accuracy ~~with~~ between the training and testing dataset is too far. At least the testing should be in a range of 70-80% accuracy. There's might be some problems when splitting the dataset for training. The best ratio should be 80:20 which means 80% for training data and 20% for testing data.

23/. Regression analysis is used for analyzing the discrete value such as the stock price prediction, house price or to find specific number of data.

24/. 2 challenges of Machine learning.

- the when the collected dataset is too large and the dataset collectors did not collect data properly it's hard to use that dataset for performing any operation. And one more thing the dataset is not fully contain the desired variable. In short is "Data collection"
- data modeling and data training

30/. Continuous attributes are discretized by the histogram. It can be measurable and can be subdivided into smaller pieces.
